Introduction to Database Systems CSE 414

Lecture 27: More Operator Costs

CSE 414 - Spring 2018

Announcements

- HW8 and WQ7 both due tonight!
- · Please fill out course evals online!
- · Last lecture on Friday

CSE 414 - Spring 2018

2019

Final Exam

- Thursday 6/7, 2:30-4:20pm
- · Location: here
- Can bring 2 letter-size sheets of notes
 - Handwritten or printed
- · More info on course website
- Review session:
 - Sunday 6/3, 2:30-5pm, SMI 102

CSE 414 - Spring 2018

Big Picture

- How to choose the "best" query plan to run? (aka query optimization)
- To answer this question we need to understand:
 - Data organization on the disk
 - Index structures and how they are used in queries
 - A way to model query "costs"
 - Compute cost for each query operator

Compute cost for each physical plan

Last topics this quarter!

CSE 414 - Spring 2018

4

Big Picture

Why do we care about all these internal details?

5

Cost Parameters

- Cost = I/O + CPU + Network BW
 - We will focus on I/O in this class
- Parameters (a.k.a. statistics):
 - **B(R)** = # of blocks (i.e., pages) for relation R
 - T(R) = # of tuples in relation R
 - V(R, a) = # of distinct values of attribute a

When a is a key, V(R,a) = T(R)
When a is not a key, V(R,a) can be anything <= T(R)

 DBMS collects statistics about base tables must infer them for intermediate results

6

Join Algorithms

- Nested loop join (short review)
- · Hash join
- · Sort-merge join

CSE 414 - Spring 2018

Nested Loop Joins

- Tuple-based nested loop R ⋈ S
- · R is the outer relation, S is the inner relation

$$\label{eq:continuous_def} \begin{split} & \underline{\text{for}} \text{ each tuple } t_1 \text{ in R } \underline{\text{do}} \\ & \underline{\text{for}} \text{ each tuple } t_2 \text{ in S } \underline{\text{do}} \\ & \underline{\text{if }} t_1 \text{ and } t_2 \text{ join } \underline{\text{then}} \text{ output } (t_1, t_2) \end{split}$$

What is the Cost?

CSE 414 - Spring 2018

Nested Loop Joins

- Tuple-based nested loop R ⋈ S
- R is the outer relation, S is the inner relation

- Cost: B(R) + T(R) B(S)
- manus timana

What is the Cost?

• Multiple-pass since S is read many times

CSE 414 - Spring 2018

Page-at-a-time Refinement

$$\label{eq:continuous_section} \begin{split} & \underline{\text{for}} \text{ each page of tuples r in R } \underline{\text{do}} \\ & \underline{\text{for each page of tuples s in S } \underline{\text{do}}} \\ & \underline{\text{for all}} \text{ pairs of tuples } t_1 \text{ in r, } t_2 \text{ in s} \\ & \underline{\text{if }} t_1 \text{ and } t_2 \text{ join } \underline{\text{then}} \text{ output } (t_1, t_2) \end{split}$$

• Cost: B(R) + B(R)B(S)

What is the Cost?

CSE 414 - Spring 2018

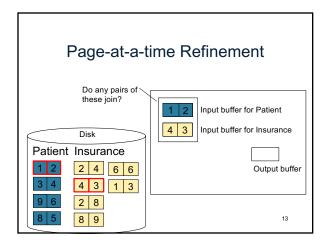

Page-at-a-time Refinement

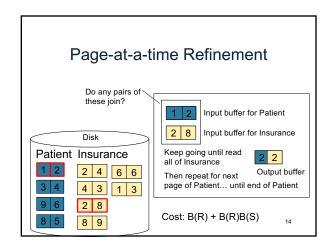

Do any pairs of these join?

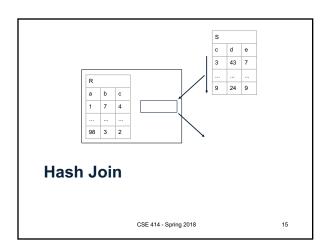

Input buffer for Patient Input buffer for Insurance

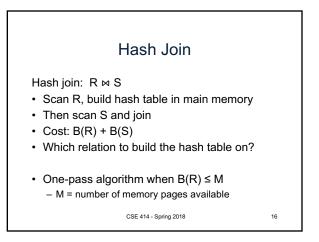

Patient Insurance

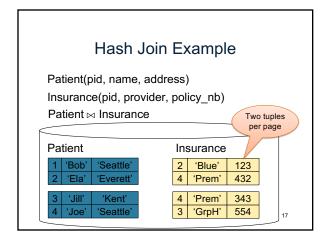

1 2 2 4 6 6 6 3 4 4 3 1 3 9 6 2 8 8 5 8 9

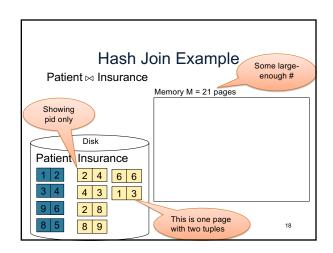

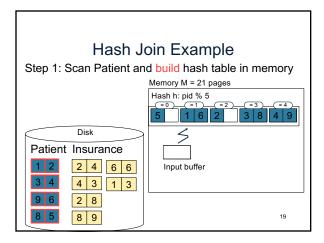

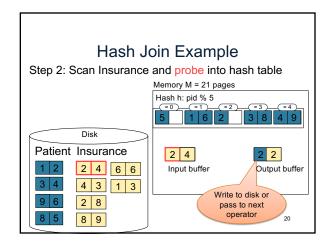

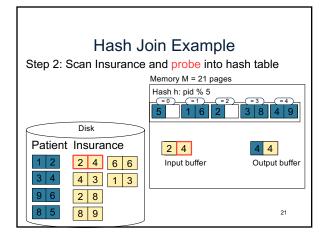

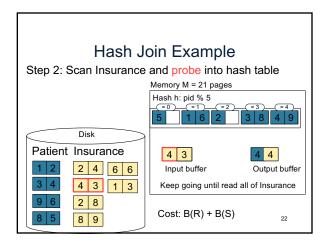

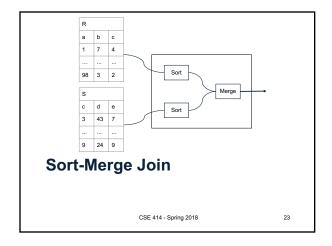

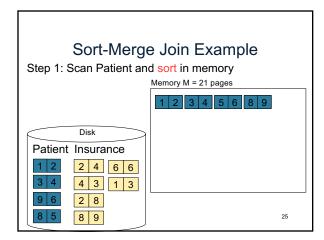

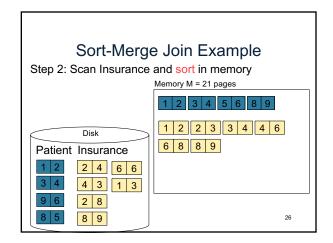

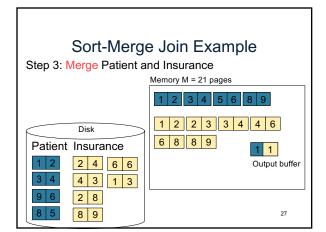

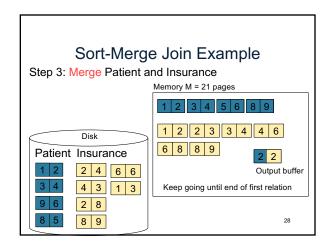

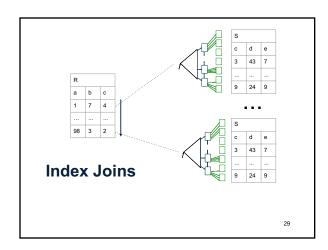

Sort-Merge Join Sort-merge join: R ⋈ S • Scan R and sort in main memory • Scan S and sort in main memory • Merge R and S • Cost: B(R) + B(S) • One pass algorithm when B(S) + B(R) <= M • Typically, this is NOT a one pass algorithm

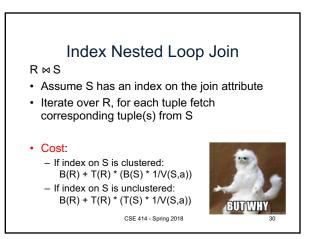

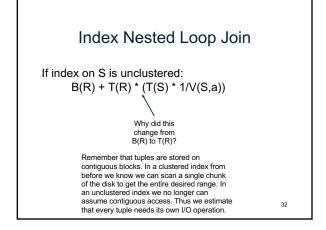

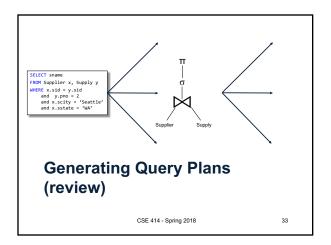

Index Nested Loop Join If index on S is clustered: B(R) + T(R) * (B(S) * 1/V(S,a))Still have to Why is the What does 1/V(S,a) represent? term T(R)? T(R) must be used because 1/V(S,a) represents the nature of the B+ Tree index. We are only we cannot assume that a whole block of R (B(R)) will scanning as much as we need have the same attribute to Note that the performance of the join on, and thus use the index join will decrease as V same index access on S for. decreases.

Review: Logical vs Physical Plans

- · Logical plans:
 - Created by the parser from the input SQL text
 - Expressed as a relational algebra tree
 - Each SQL query has many possible logical plans
- Physical plans:
 - Goal is to choose an efficient implementation for each operator in the RA tree
 - Each logical plan has many possible physical plans

CSE 414 - Spring 2018

```
Supplier(sid, sname, scity, sstate)
Supply(sid, pno, quantity)

Review: Relational Algebra

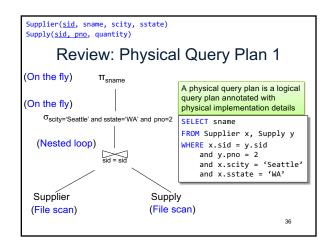

SELECT sname
FROM Supplier x, Supply y
WHERE x. sid = y. sid
and y.pno = 2
and x. scity = 'Seattle'
and x. sstate = 'WA'

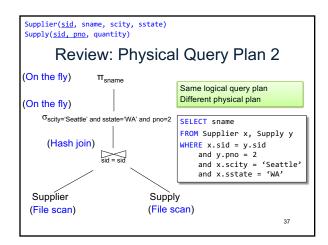

Relational algebra expression is also called the "logical query plan"

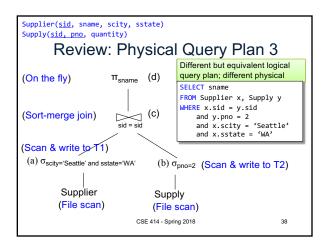

Supplier Supply

CSE 414-Spring 2018

```

Query Optimization: Overview

- · Compute cost of each operator
 - This depends on:
 - Table statistics (# of tuples etc)
 - Algorithm used
- Cost of a physical plan = sum(each operator cost)
- Cost each plan and choose the one with lowest cost

CSE 414 - Spring 2018
